

Session 2:

Introduction into fMRI analysis

Dr. Elena Galeano Weber

e.galeano-weber@dipf.de

Education and Human Development & Individualized Learning Laboratory, DIPF | Leibniz
Institute for Research and Information in Education

Recap of last session

MR basics:

- Scanner = magnet + RF transmitter
- MRI relies on the magnetic properties of the tissue
- MR images are 3D “pictures” composed of voxels with one value per voxel
- Most common 3D files: NifTi (.nii) and compressed NifTi (nii.gz).
- Spatial resolution depends on scanner strength

Type of images:

- MR images can be roughly grouped into anatomical and functional images
 - Anatomical images (usually one volume) have higher spatial resolution than functional images (usually several volumes).
 - TR = time to collect one brain volume.
 - Runs = acquisition windows.
- PsyMsc4, Summer Semester 2025

Preprocessing:

- Slice-time correction
- Magnetic field distortions
- Intensity inhomogeneities
- Motion correction
- Registration
- Normalization

Recap of last session

MR images are a collection of voxels (3D matrix) with a value (a number) in each cell.

The value represents a different thing for anatomical and functional images.

Functional MRI. BOLD signal.

Functional images are used to study brain activity.

But what does brain activity look like when looked through a MR scanner?

Functional MRI. BOLD signal.

If we plot the voxels values over time...

Functional MRI. BOLD signal.

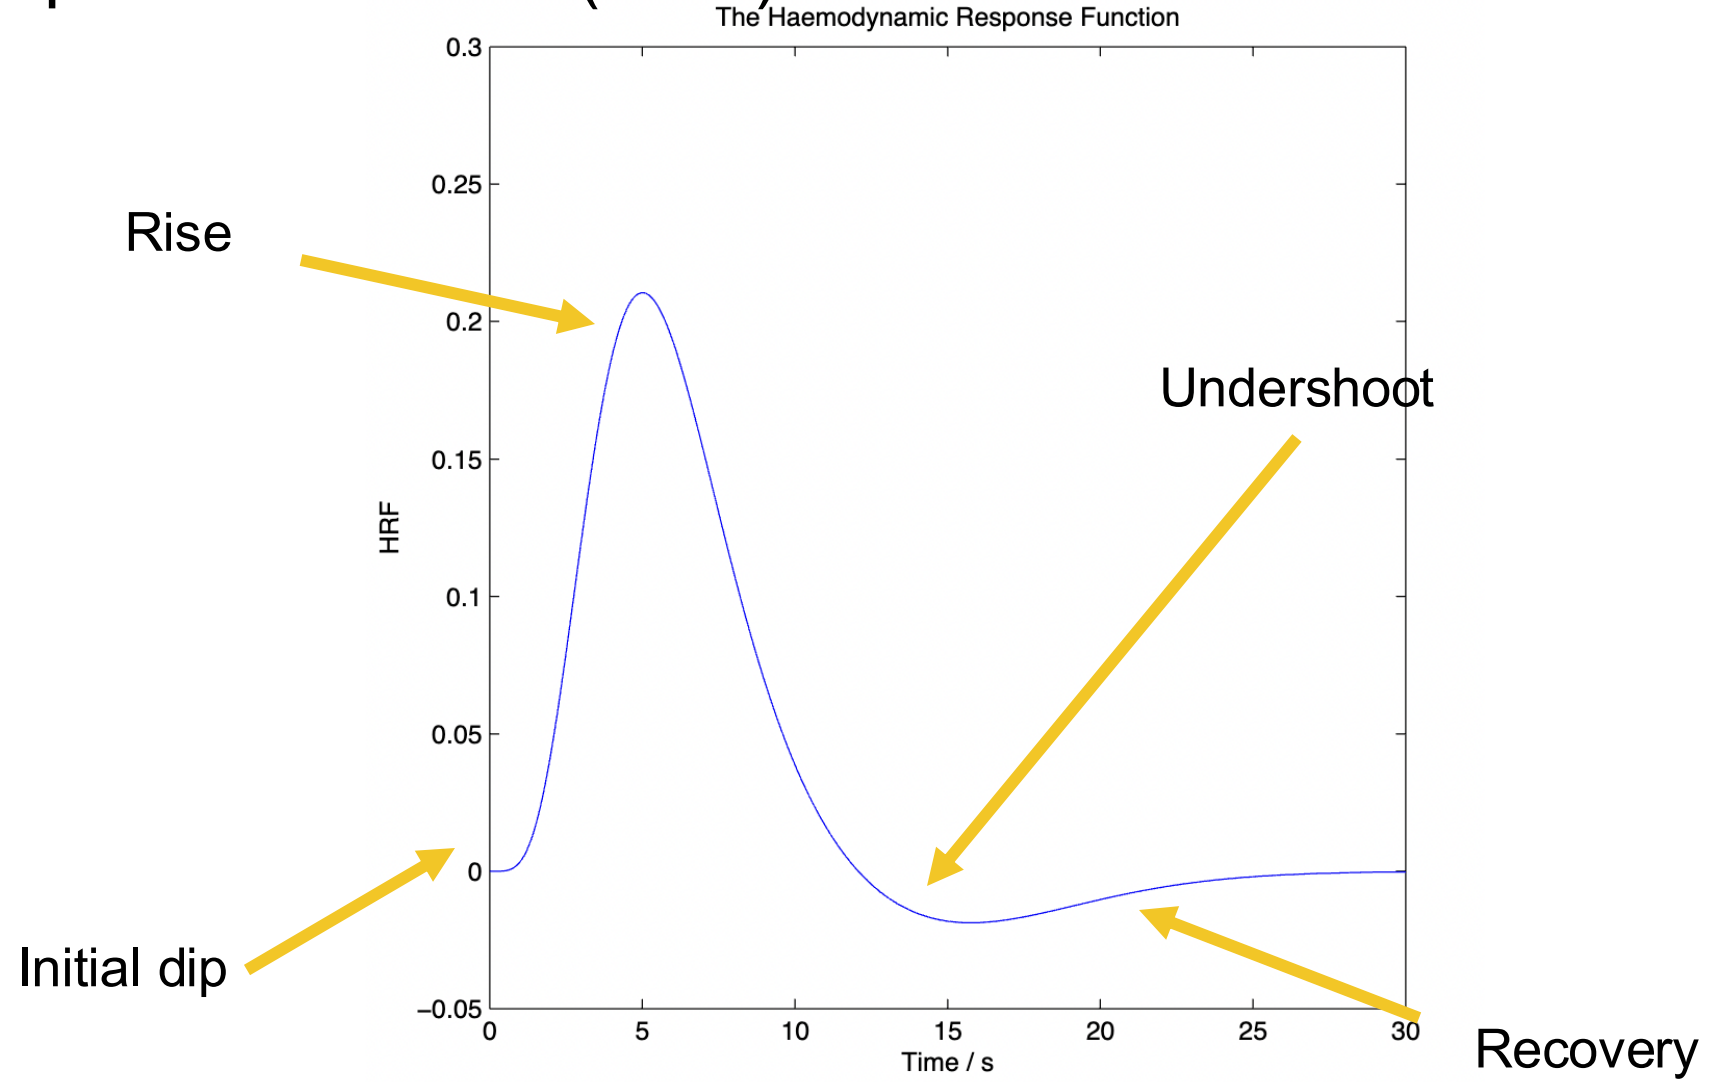

Functional images are used to study brain activity.

What we are recording in our functional sequences is actually blood oxygen level dependent (BOLD) signal.

But what does brain activity (BOLD) look like when looked through a MR scanner?

Functional MRI. BOLD signal. The Hemodynamic Response Function (HRF)

Functional MRI. BOLD signal.

This is the 'ideal' response to stimulation but, of course, the measured signal is noisier.

Measured signal in 1 voxel over many volumes

GLM. Generalized Linear Models

If you remember your stats class...

Linear Regression: Single Variable

$$\boxed{\hat{y}} = \beta_0 + \beta_1 \boxed{x} + \boxed{\epsilon}$$

redicticted output Intercept Slope Input Error

from Wikipedia

GLM. Generalized Linear Models

If you remember your stats class...

Linear Regression: Single Variable

$$\hat{y} = \beta_0 + \beta_1 x + \epsilon$$

\hat{y} : predicted output
 β_0 : Intercept
 β_1 : Slope
 x : Input
 ϵ : Error

from Wikipedia

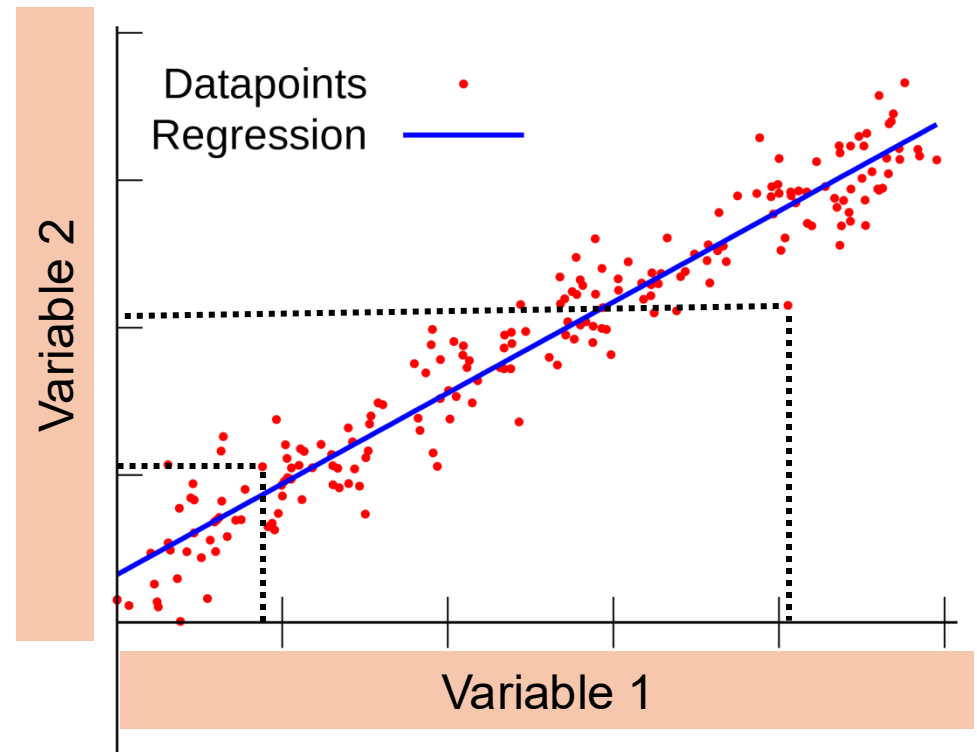

GLM. Generalized Linear Models

If you remember your stats class...

Linear Regression: Single Variable

$$\hat{y} = \beta_0 + \beta_1 x + \epsilon$$

\hat{y} : predicted output
 β_0 : Intercept
 β_1 : Slope
 x : Input
 ϵ : Error

from Wikipedia

GLM. Generalized Linear Models

If you remember your stats class...

Linear Regression: Single Variable

$$\hat{y} = \beta_0 + \beta_1 x + \epsilon$$

\hat{y} : predicted output β_0 : Intercept β_1 : Slope x : Input ϵ : Error

QUESTION:

What does the beta value represent?

from Wikipedia

GLM. Generalized Linear Models

If you remember your stats class...

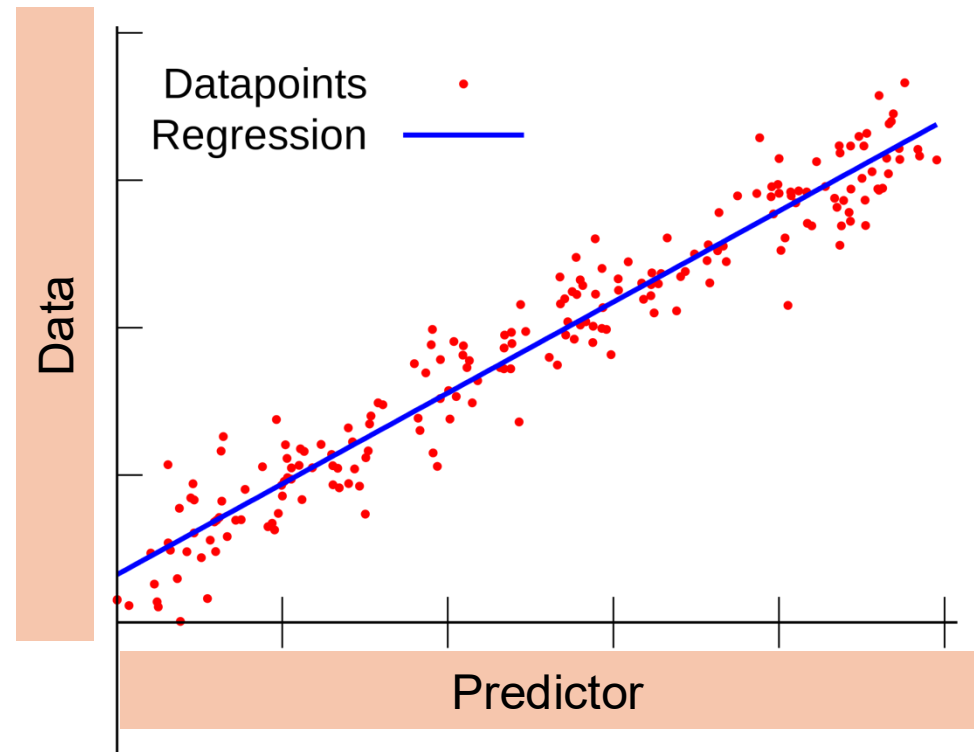

Linear Regression: Single Variable

$$\hat{y} = \beta_0 + \beta_1 x + \epsilon$$

redicted output Intercept Slope Input Error

QUESTION:

What does the beta value represent?

from Wikipedia

GLM. Generalized Linear Models

Regression is the usual approach for analysis of fMRI signals.

Measured signal in 1 voxel over many volumes

GLM

A practical example. Can we find voxels that respond to ANIMAL FACES?

Task
(visual stim.)

Voxel
activity

Task

GLM

A practical example. Can we find voxels that respond to ANIMAL FACES?

Voxel activity

Task model

Response model

GLM

A practical example. Can we find voxels that respond to ANIMAL FACES?

Voxel activity

Task model

Response model

Now we can use regression to obtain an estimate (**beta**) of how much our response model explains our BOLD signal in our **voxel**.

GLM

A practical example. Can we find voxels that respond to ANIMAL FACES?

Voxel activity

Task model

Response model

If run for every voxel, we will get one beta estimate per voxel, i.e., a beta map

GLM

A practical example. Can we find voxels that respond to ANIMAL FACES?

Voxel activity

Task model

Response model

QUESTION: What would the value in each voxel of the beta map represent?

GLM

A practical example. Can we find voxels that distinguish DOGS FACES from ALPACAS FACES?

Voxel activity

Task model

Regressor 1

Regressor 2

GLM

QUESTION: What would the value in each voxel of the beta map represent?

Voxel activity

Task model

Regressor 1

Regressor 2

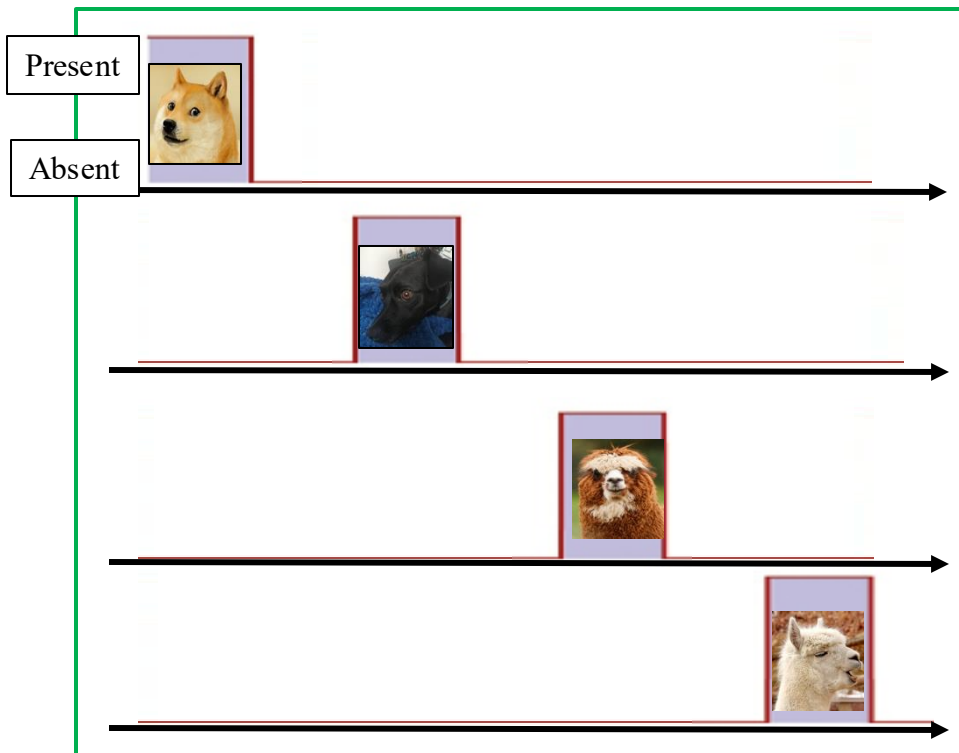

GLM

Another practical example. Can we find voxels that distinguish each CHARACTER?

Voxel activity

Task model

We can have a regressor and, therefore, a beta for **every** trial.

Beta1

Beta2

Beta3

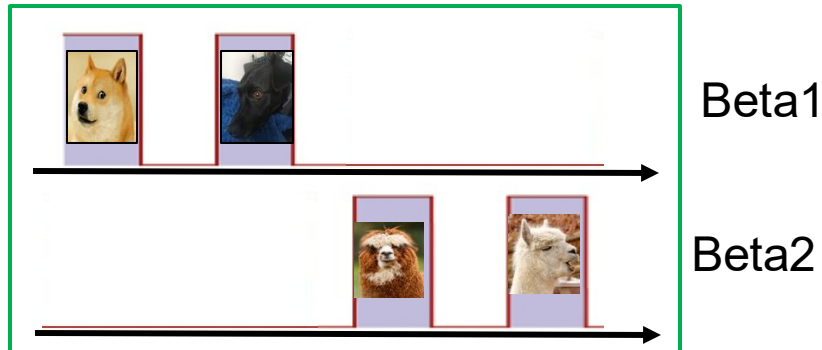

Beta4

GLM

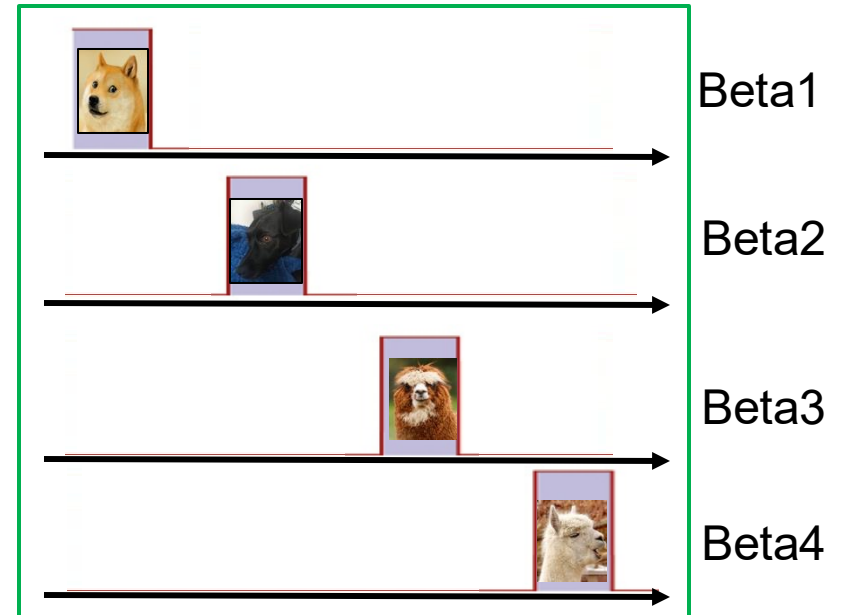

Different GLM (task) models. LSU is widely used for **univariate** analysis while LSA (or more complex models) are often used for **multivariate** analysis.

Least-Squares
Unitary (LSU)

“One beta per condition is estimated”

Least-
Squares All
(LSA)

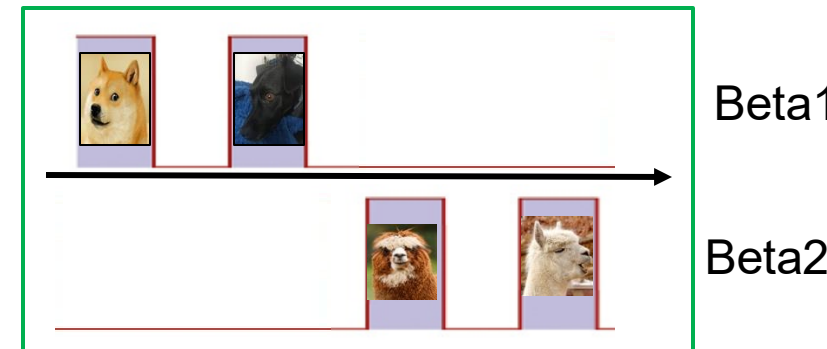

“One beta per trials is estimated”

There are also more complex models: Least-Squares Separate (LSS), LS-1, LS-2...

GLM

Interim recap.

- fMRI sequences measure BOLD signal.
- Regression is the usual approach to analyze BOLD signal change.
- We use the condition (or stimulus) time course to model BOLD time course in each voxel.
- Regression will give us beta estimates for each voxel.
- The number (and meaning) of each beta estimates depends on the task model that we use.

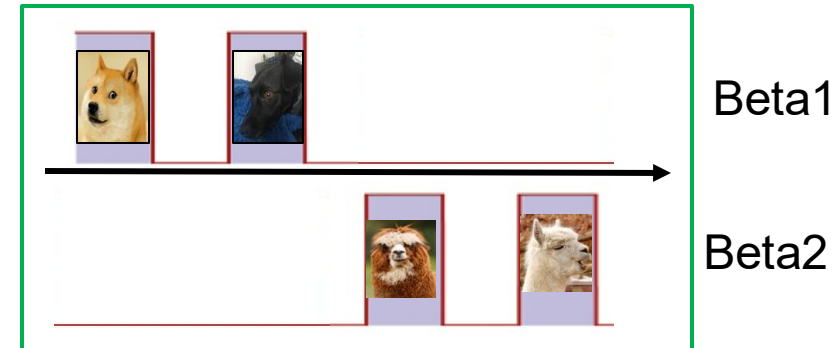

GLM

Back to theory.

We have seen that (task) regressors can be used to check if the time course of our variables correlates with signal change in the brain.

But the BOLD signal can also change with *stuff* other than our variables.

We do not want our results to be driven by (confounded with) other *stuff*.

Linear Regression: Single Variable

$$\hat{y} = \beta_0 + \beta_1 x + \epsilon$$

Diagram illustrating the Linear Regression: Single Variable equation:

- \hat{y} : Predicted output
- β_0 : Intercept
- β_1 : Slope
- x : Input
- ϵ : Error

A yellow arrow points from a box labeled "stuff" to the error term ϵ .

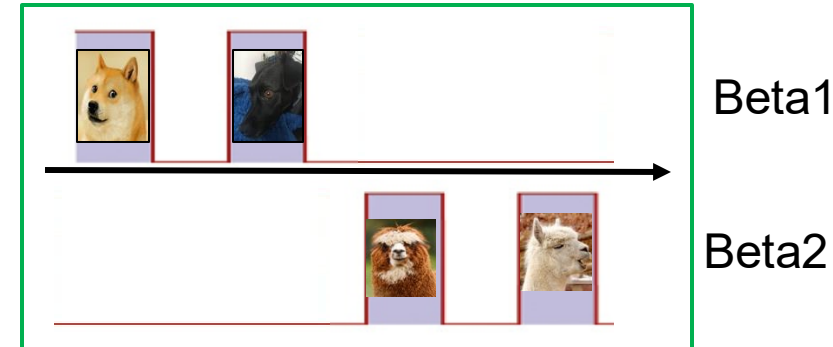

GLM

Back to theory.

We have seen that (task) regressors can be used to check if the time course of our variables correlates with signal change in the brain.

But the BOLD signal can also change with *stuff* other than our variables.

Enter: Nuisance/confound regressors.

Linear Regression: Single Variable

$$\hat{y} = \beta_0 + \beta_1 x + \epsilon$$

Diagram illustrating the Linear Regression: Single Variable equation:

- \hat{y} : Predicted output
- β_0 : Intercept
- β_1 : Slope
- x : Input
- ϵ : Error

A box labeled "stuff" is connected by a yellow arrow to the Error term (ϵ), indicating that "stuff" represents unmodeled variance or confounding factors.

GLM

Nuisance regressors.

What can affect signal *change* in a given voxel?

- Head motion.
- Breathing.
- Heart rate.
- Scanner drift.
- ...

GLM

Nuisance regressors.

What can affect signal *change* in a given voxel?

- Head motion.
- Breathing.
- Heart rate.
- Scanner drift.
- ...

What should nuisance regressor look like?

One **value** per each **datapoint** in our data.

GLM

Nuisance regressors.

Some measures that we get *for free*...

from `data_fmri-analysis_intro/process-specific/preproc_data/fmriprep/sub-009.html`

GLM

Nuisance regressors.

If we can identify the time course of each factor that we believe can influence our signal change, we can add them in our model.

GLM

Nuisance regressors.

Betas estimated from nuisance regressors are usually not of interest for our analysis, but they can account for an important portion of the variance in our signal.

It is important to know *how many* nuisance regressors we will include in our model because that will change the number of betas we get out of the regression!

Linear Regression: Single Variable

$$\boxed{\hat{y}} = \beta_0 + \beta_1 \boxed{x} + \boxed{\epsilon}$$

Diagram illustrating the components of the Linear Regression equation:

- \hat{y} : Predicted output (red box)
- β_0 : Intercept
- β_1 : Slope
- x : Input (blue box)
- ϵ : Error (orange box)

An arrow points from the Error term (ϵ) to a box labeled "Error to be minimized".

GLM

Nuisance regressors.

QUESTION: Should we convolve our nuisance regressors with an HRF?

Linear Regression: Single Variable

$$\boxed{\hat{y}} = \beta_0 + \beta_1 \boxed{x} + \boxed{\epsilon}$$

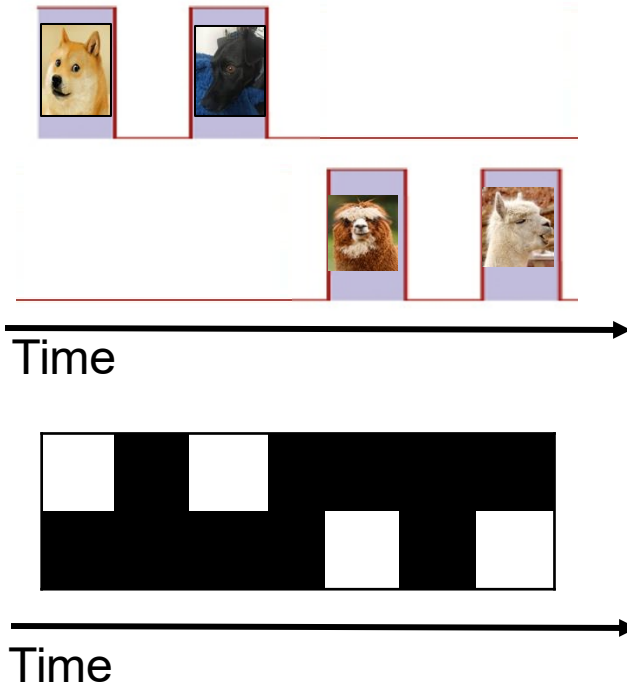

Diagram illustrating the Linear Regression equation with components labeled:

- \hat{y} : predicted output
- β_0 : Intercept
- β_1 : Slope
- x : Input
- ϵ : Error

An arrow points from the Error term (ϵ) to a box labeled "Error to be minimized".

GLM

GLM

General recap.

- fMRI sequences measure BOLD signal.
- Regression is the usual approach to analyze BOLD signal change.
- We use the condition (or stimulus) time course to model BOLD time course in each voxel.
- Regression will give us beta estimates for each voxel.
- The number (and meaning) of each beta estimates depends on the task model that we use.
- Nuisance regressors can help “cleaning” our signal.
- Estimations on head motions are the most common nuisance regressors used.
